The 80/20 Rule

71

**Figure 6.1 Random and Scale-Free Networks.** *The degree distribution of a random network follows a bell curve, telling us that most nodes have the same number of links, and nodes with a very large number of links don't exist (top left). Thus a random network is similar to a national highway network, in which the nodes are the cities, and the links are the major highways connecting them. Indeed, most cities are served by roughly the same number of highways (bottom left). In contrast, the power law degree distribution of a scale-free network predicts that most nodes have only a few links, held together by a few highly connected hubs (top right). Visually this is very similar to the air traffic system, in which a large number of small airports are connected to each other via a few major hubs (bottom right).*

# What are we talking about this time?

1. Graphs & Networks
2. Again, the Internet & The Web
3. Search Engines
4. The Web 2.0
5. Communities & UGC
6. Social Networks
7. Web Presence

Figure 11.1 Paul Baran's Networks. In 1964, Paul Baran began thinking about the optimal structure of the Internet. He suggested that there were three possible architectures for such a network—centralized, decentralized, and distributed—and warned that both the centralized and decentralized structures that dominated communications systems of the time were too vulnerable to attack. Instead, he proposed that the Internet should be designed to have a distributed, mesh-like architecture. (Reproduced with permission of Paul Baran.)

# Your main printed book

**Linked** is a book first published in 2002 by **Albert-László Barabási**, an American physicist of Hungarian origins born in 1967, and best known for his research in the field of networks.

As far as these lectures and your assessment are concerned, **Linked** is the main **printed book** you have to read, understand, and be able to tell about.

Apart from the initial pages of **Metadata**, all the rest is downloadable files – like this you’re reading now – and links to be visited.

But I promise: when I say you have to “read, understand, study, and be able to tell about” this book, I mean it.

# Your main printed author

Barabási A.-L., *Linked. How Everything Is Connected to Everything Else and What It Means for Business, Science, and Everyday Life*, Perseus, Cambridge, Massachusetts 2002 (chapters 1-12)

image credit to [hxdata.chisa.edu.cn](http://hxdata.chisa.edu.cn)

So, let's begin with reading pages 1 through 8 of *Linked* – **loud**.

But... Wait a minute!

Pages 1 through 8 of *Linked* contain 2,523 words, and 15,302 digits...

If we read them, it will take more than **16 minutes**. Too much!

# “Linked” – Excerpts from pages 1 through 8

Let's read **some excerpts only**. Your lecturer has abridged pages 1 through 8.

(Well... this cutting has left a logical gap, in fact. But you will certainly not notice it and get the meaning just the same.)

Through the following three pages of this presentation, we can read loud excerpts from pages 1 through 8, totaling **802 words**, and **3,126 digits**.

Our reading should take less than 4 minutes.

(In case you need to listen to the full introduction, or simply know more about **Linked** before holding the book in your hands, find an **Mp3** file at [https://kiwimilano.it/dct/links\\_2021-2022.asp#Networks](https://kiwimilano.it/dct/links_2021-2022.asp#Networks))

image credit to [hxdata.chisa.edu.cn](http://hxdata.chisa.edu.cn)

# Yahoo!

“FEBRUARY 7, 2000, SHOULD HAVE BEEN a big day for Yahoo. Instead of the few million customers that daily flock to the Internet search engine, billions tried to enter the site. Such exploding **popularity** should have turned the company into the most valuable asset of the new economy.

There was a problem, however. They all arrived **at the exact same time** and not one of them asked for a stock quote or a pecan pie recipe. Rather, they all sent, in scripted computer language, the message ‘Yes, I heard you!’

The next day the royals of the Web, Amazon.com, eBay, CNN.com, ETrade, and Excite, fell **under the same spell**: They too were obliged to serve billions of ghosts making the same fruitless inquiry that had handicapped Yahoo. True consumers, with shiny credit cards ready for purchases, were forced to wait on the side lines.”

# ... Yahoo! (continued)

“Early news reports construed the shutdown of the leading e-commerce sites to be the work of a group of **sophisticated hackers**.

Surprisingly, the high-profile operation of the Federal Bureau of Investigation did not lead to the much-anticipated cyberterrorist organization. Instead, the FBI arrived at the suburban home of **a Canadian teenager**.

Hiding behind the pseudonym MafiaBoy, this **fifteen-year-old** successfully halted the operations of billion-dollar companies with access to the best computer security experts in the world.”

## ... and Paul...

“The early Christians were nothing more than a renegade Jewish sect. There is no historical evidence that their spiritual leader, Jesus of Nazareth, ever intended to have **an impact** beyond Judaism. His ideas were difficult and controversial enough for Jews, and reaching the gentiles seemed particularly hopeless. Despite the odds, close to **two billion people** call themselves **Christian** today.

How did that happen? How did the **unorthodox beliefs** of a small and disdained Jewish sect come to form the basis of the Western world’s dominant religion?

Many credit the triumph of Christianity to the message offered by the historical figure we know today as **Jesus of Nazareth.**”

# ... Paul (continued).

“Today, marketing experts would describe his message as ‘sticky’— it resonated and was passed down by generations while **other religious movements fizzled and died**. But credit for the success of Christianity in fact goes to an orthodox and pious Jew who never met Jesus.

While his Hebrew name was Saul, he is better known to us by his Roman name, **Paul**. Paul’s life mission was to curb Christianity. He used scourging, ban, and excommunication to uphold the traditions and to force the deviants to adhere to Jewish law.

Nevertheless, according to historical accounts, this fierce persecutor of Christians underwent a sudden **conversion** in the year 34 and became **the fiercest supporter of the new faith**, making it possible for a small Jewish sect to become the dominant religion in the Western world for the next 2,000 years.”

# Thinking in terms of networks

“There are huge differences between MafiaBoy and Paul: MafiaBoy’s was an act of destruction. Paul, despite his initial intentions, became a bridge builder between early Christian communities.

But the two have something important in common: Both were **masters of the network**.

Paul and MafiaBoy succeeded because **we are all connected**. Our biological existence, social world, economy, and religious traditions tell a compelling story of interrelatedness. As Jorge Luis Borges put it, ‘**everything touches everything**.’

This book has a simple aim: **to get you to think networks**. It is about how networks emerge, what they look like, and how they evolve. It shows you a Web-based view of nature, society, and business, a new framework for understanding issues ranging from democracy on the Web to **the vulnerability of the Internet** and the spread of viruses.”

# Euler in Königsberg

As far as we now, the first man who ever had a Web-based view of something was a Swiss mathematician, **Leonhard Euler** (1707-1783), who wanted to solve a mind puzzle.

The town of Königsberg is crossed by a river, the Pregel, having an island connected by seven bridges. Königsbergers wondered: “Can one walk across the seven bridges and never cross the same one twice?”

# Euler's, his graph, and his proof

Euler solved the problem by thinking of islands and walks over bridges in mathematical terms, as **points** and **lines**, making up a **graph**.

What was Euler's proof?

To quote Barabási, “Nodes with an **odd number** of links must be either the **starting** or the **end point** of the journey. A continuous path that goes through all bridges can have **only one starting** and **one end** point. Thus, such a path cannot exist on a graph that has **more than two nodes** with an **odd number of links**.”

Figure 2.1 Königsberg Bridges. The layout of Königsberg before 1875, with Kneiphof island (A) and the land area D caught between the two branches of the Pregel River. Solving the Königsberg problem meant finding a route around the city that would require a person to cross each bridge only once. In 1736, Leonhard Euler gave birth to graph theory by replacing each of the four land areas with nodes (A to D) and each bridge with a link (a to g), obtaining a graph with four nodes and seven links. He then proved that on the Königsberg graph, a route crossing each link only once does not exist.

# From graphs to networks

But the proof as such is not relevant here. We're not supposed to study mathematics or be mathematicians. What matters is that in the 18C someone began to have a **web-based** view of the world.

During the centuries, we have come to call Euler's points as **nodes**, his lines as **links**, and his graphs as **networks**.

Today, we call a **link** a connection between two webpages.

Well, Euler's Königsberg is where it all began.

Figure 2.1 Königsberg Bridges. The layout of Königsberg before 1875, with Kneiphof island (A) and the land area D caught between the two branches of the Pregel River. Solving the Königsberg problem meant finding a route around the city that would require a person to cross each bridge only once. In 1736, Leonhard Euler gave birth to graph theory by replacing each of the four land areas with nodes (A to D) and each bridge with a link (a to g), obtaining a graph with four nodes and seven links. He then proved that on the Königsberg graph, a route crossing each link only once does not exist.

# The Internet as a network

As you know, webpages travel by the millions along **nodes** of the Internet – which is clearly **a network**.

In 1964, **Paul Baran** advised on the **architecture** of the Internet, which was soon to come, underlining that

- a **centralized** one is too vulnerable;
- a **decentralized** one might be better;
- but the only real solution would be offered by a **distributed network**.

Today web pages always arrive, somehow, because they may **travel** through the Internet following **any of very many available paths**.

The Awakening Internet

145

**Figure 11.1 Paul Baran's Networks.** *In 1964, Paul Baran began thinking about the optimal structure of the Internet. He suggested that there were three possible architectures for such a network—centralized, decentralized, and distributed—and warned that both the centralized and decentralized structures that dominated communications systems of the time were too vulnerable to attack. Instead, he proposed that the Internet should be designed to have a distributed, mesh-like architecture. (Reproduced with permission of Paul Baran.)*

# The Internet, more or less

As you may remember, we introduced this point already when dealing with digital.

- A **client** computer – say, your computer – sends to a **server** computer a message, which is split in **packets of bytes** according to the **TCP** (Transmission Control Protocol). The packets are **sent** across the Internet.
- Typically, the message may ask to reach a web page according to the **http** (hypertext transfer) **protocol**, request to get a specific file according to the **ftp** (file transfer) **protocol**, or contain a text according to the **e-mail protocol**.
- Every packet contains, among other things, the “**names**” of the target server and the client server – to make it short, their **IP** (Internet Protocol) **addresses**.
- It **doesn't matter which ways every packet travels across the Internet** to reach the server and then be back. It matters that packets “**know**” **which server** they must reach, and **which position every packet has to regain** at the arrival.

# Internet packets

Well, actually things are a bit more complicated. This example is about an e-mail message

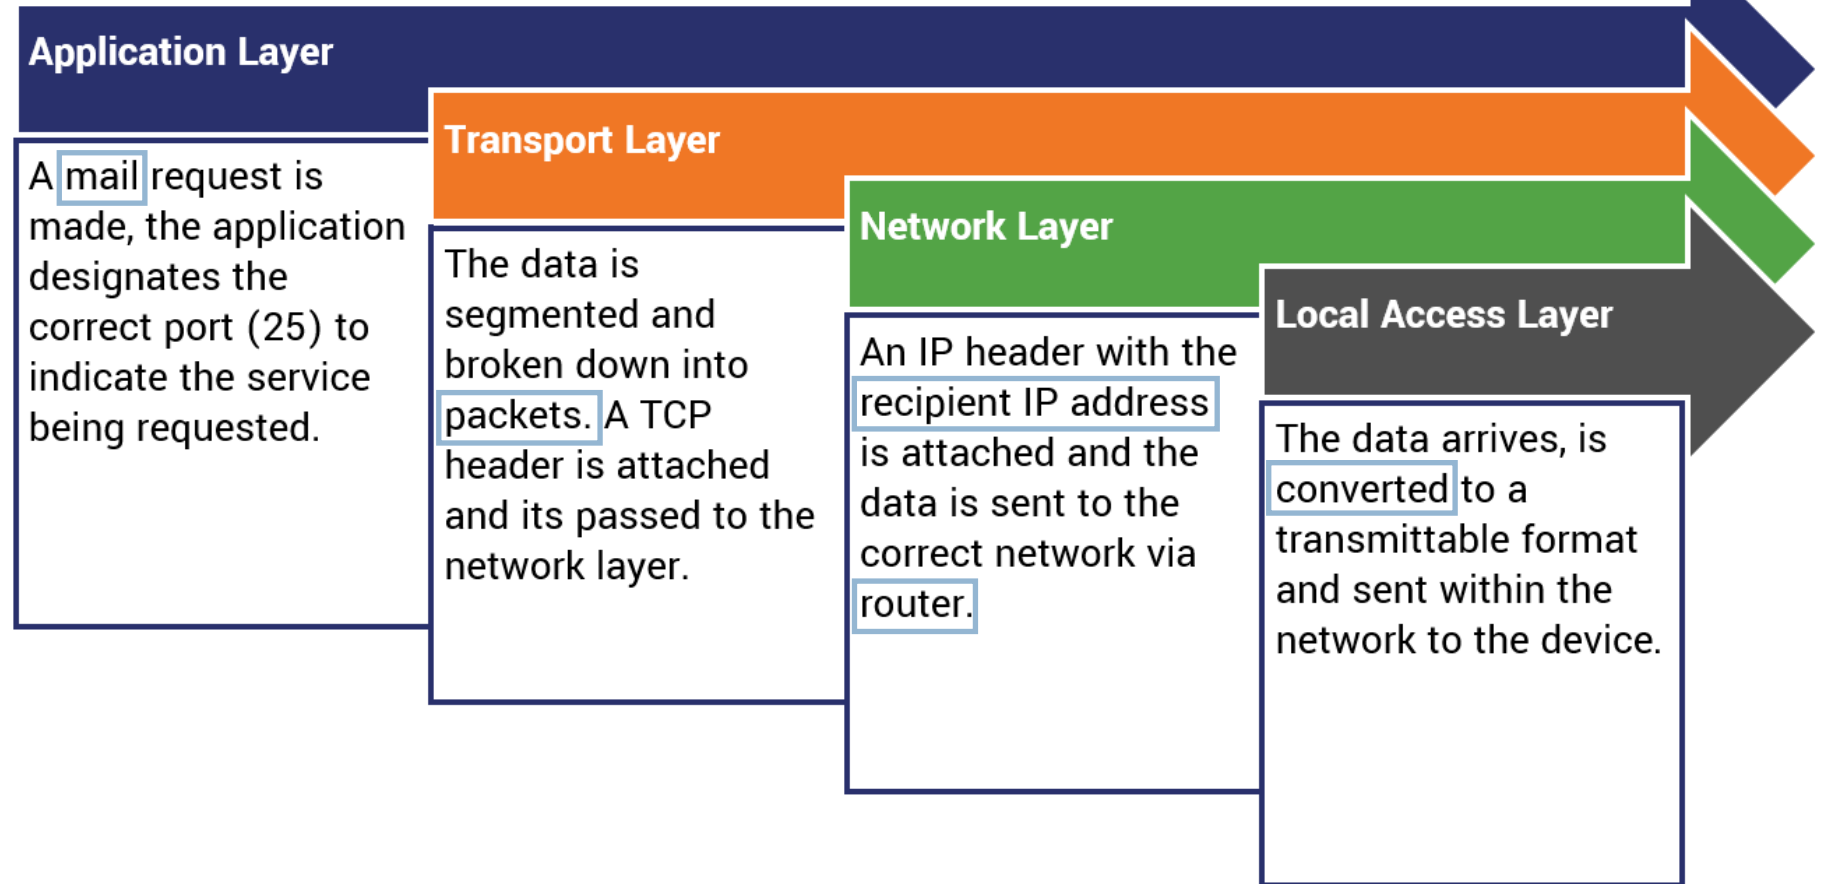

image credit to [VpnStore](#)

# Internet routing

Anyway, **splitting** and **routing** across a distributed network are the **crucial** factors.

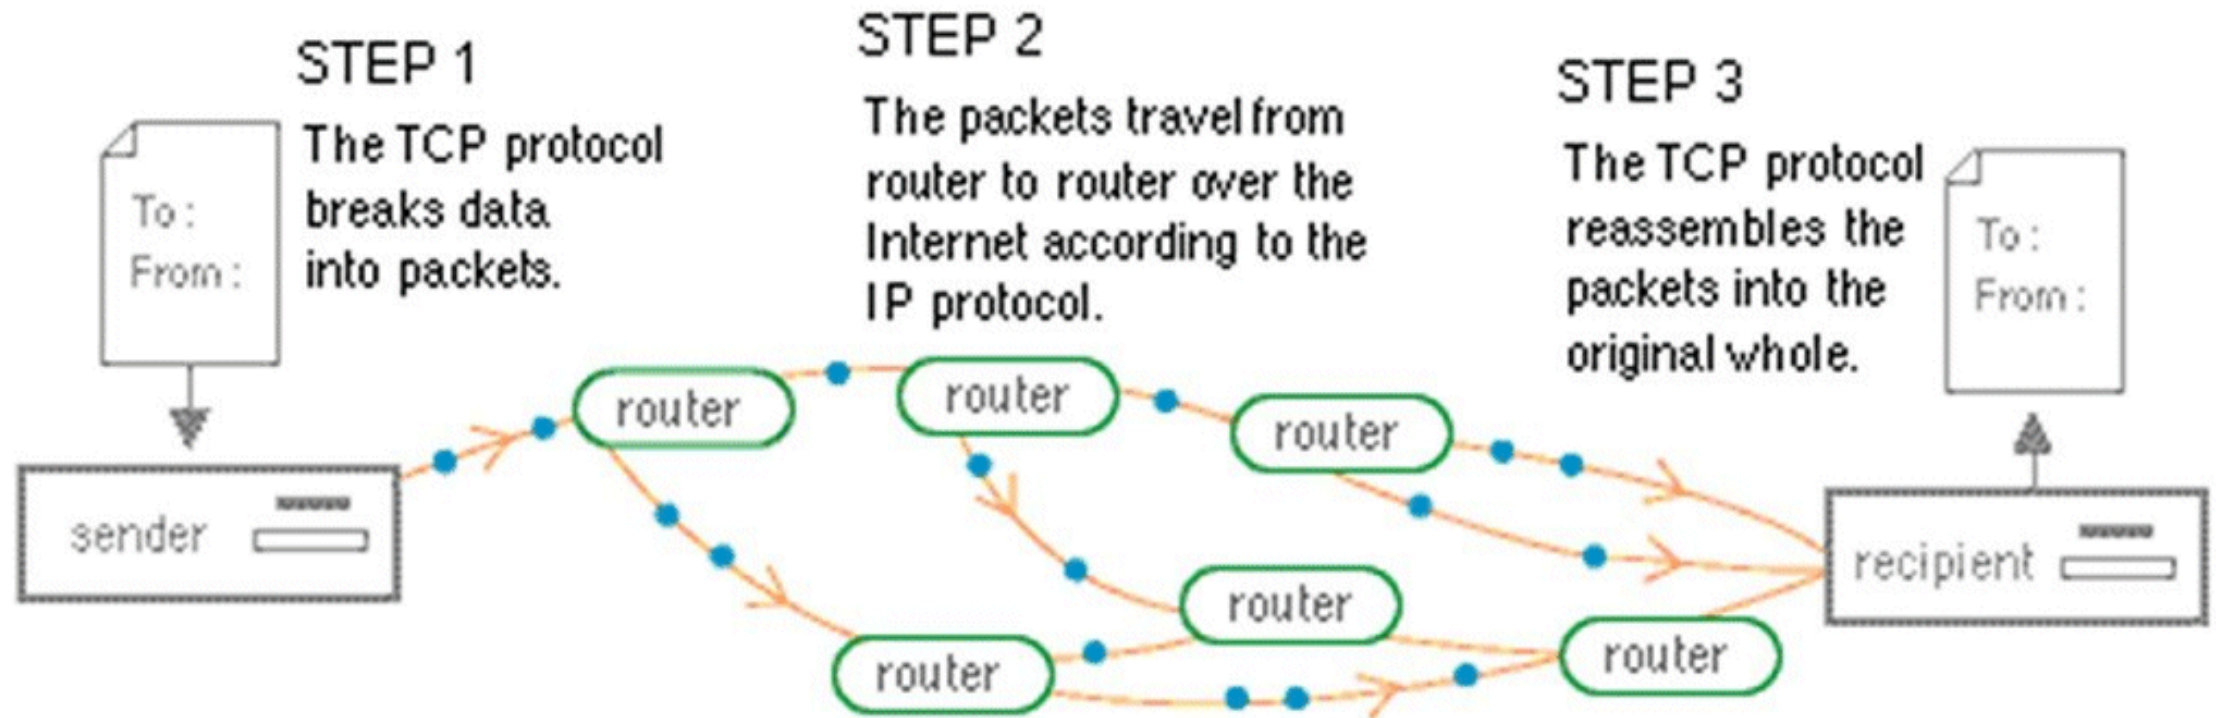

image credit to [Pinterest](#)

# Scale-free networks, and hubs

Still talking about different sorts of networks, Barabási has proved that most networks are **not like highway networks** which connect major cities one another, each city having about the same number of roads or **links**.

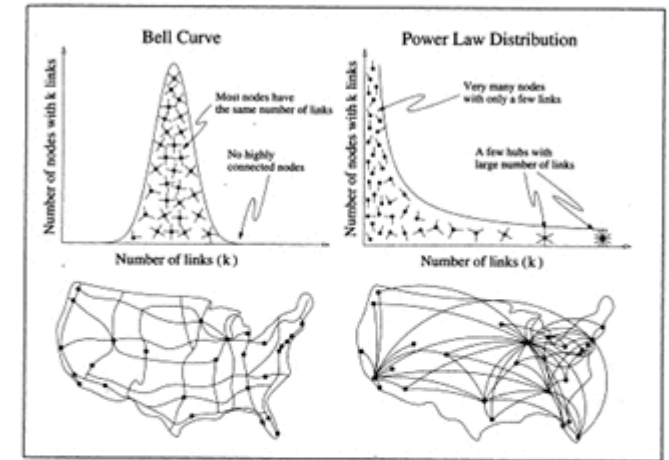

Nodes of such “highway” networks connect rather regularly, **on a scale**, according to a **Bell Curve**.

Most networks, instead, behave **like airlines** using a few hub airports. Some nodes are **hubs**, having many more links than the other nodes.

Most networks connect according to a **Power Law**. Most networks are **scale-free**.

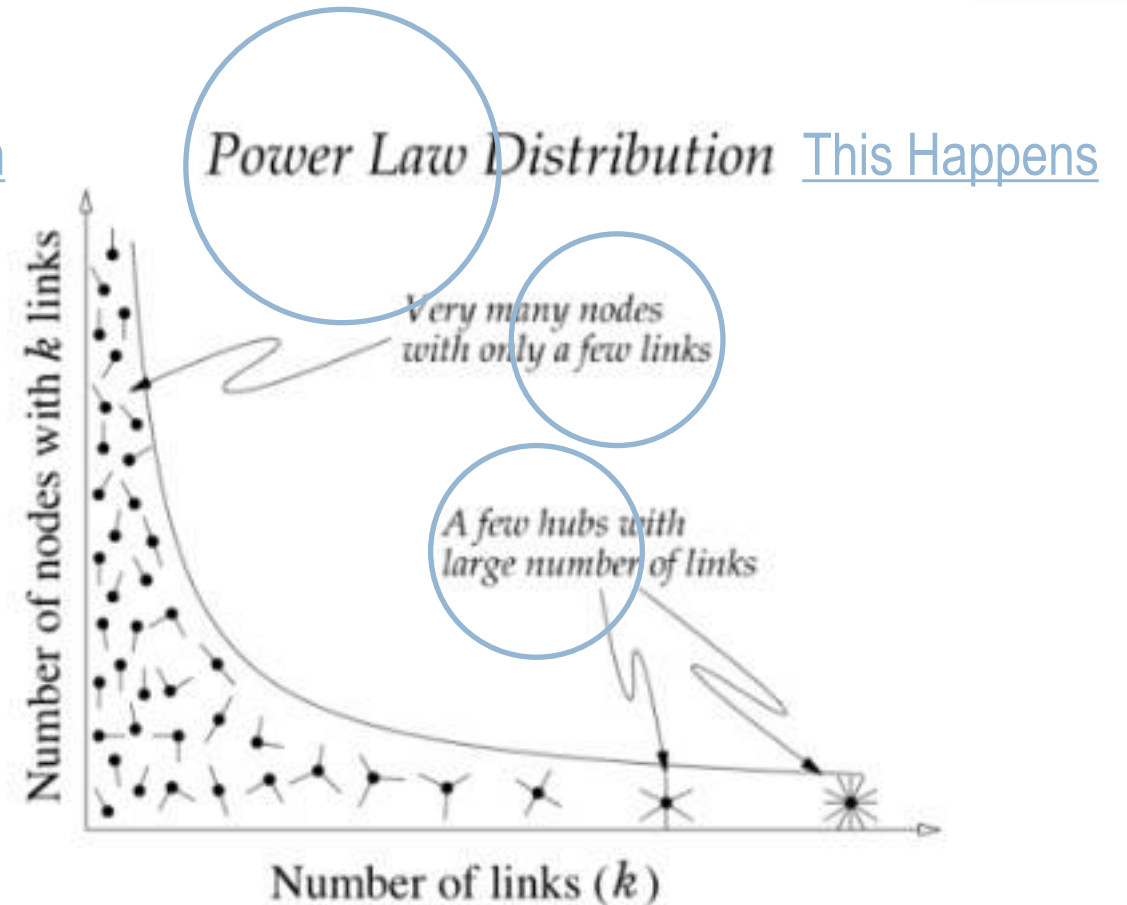

The 80/20 Rule

71

**Figure 6.1 Random and Scale-Free Networks.** *The degree distribution of a random network follows a bell curve, telling us that most nodes have the same number of links, and nodes with a very large number of links don't exist (top left). Thus a random network is similar to a national highway network, in which the nodes are the cities, and the links are the major highways connecting them. Indeed, most cities are served by roughly the same number of highways (bottom left). In contrast, the power law degree distribution of a scale-free network predicts that most nodes have only a few links, held together by a few highly connected hubs (top right). Visually this is very similar to the air traffic system, in which a large number of small airports are connected to each other via a few major hubs (bottom right).*

# Bell Curve and Power Law

Number of nodes in the axis of ordinates, number of links in the axis of abscissae.

# The Web & search engines

Does the **World-Wide Web** behave like most networks? Yes, it does. A few nodes (or websites) have **many more links** than all the others. They are **hubs**.

Obviously, since **search engines** like Google or Bing link to a lot of other websites, they are much “stronger” websites than the others. They are **hubs**.

And which websites do search engines **display first**, when you search according to your **keywords**? Search engines display first the websites with **a higher number of links**, according to the chosen keywords. They display first the most linked sites.

Conclusion? The **more we link**, the **better** our website **ranks** on search engines.

(Of course, the relationship between number of links and popularity is not a direct one. The reliability of the website and its maintenance also matter, as does the proportion between out links and backlinks. We will go deeper into this when dealing with analytics.)

# Please, do not become islands...

A few **hubs** with a large number of links makes the **Central Core** of the Web.

Conversely, most websites are either **IN** or **OUT Continents**.

They tend to become **Tendrils** – if still indexed by search engines – and can ultimately turn into **Islands**.

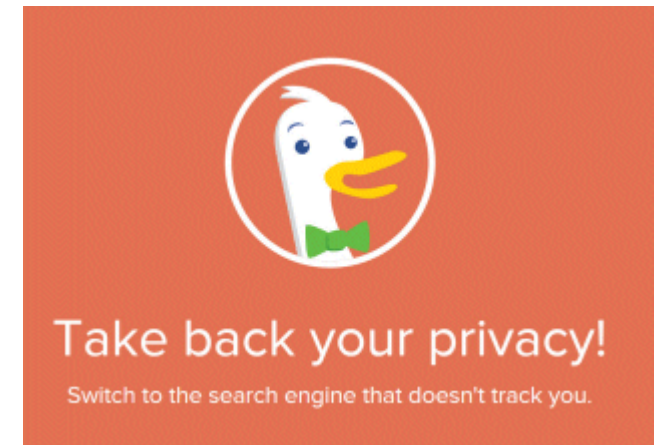

# Web oligopolies – like search engines

Since the Web behaves like most networks, it is not surprising that some websites belong to an oligopoly of **hubs** and become **incrementally** stronger.

Each time we **search** in Google, Bing or DuckDuckGo, we accept and **confirm** that Google, Bing or DuckDuckGo are **strong**. We enhance their status as **hubs**.

But there's more. Think about this, the social way...

# Social oligopolies – like Facebook

Each time we post something on Facebook, we **contribute** to make Facebook **stronger**.

And, moving to tourism, each time a tourist comments on **TripAdvisor**, she/he contributes to make TripAdvisor **stronger**.

Why? Because every time someone posts on Facebook or TripAdvisor a piece of **User-Generated Content (UGC)**, she/he confirms that they are **hubs**, often adds **new links** to them, and makes them **stronger**.

# Ranking, SEO

The evaluation that search engines provide of a webpage, also called the webpage's “**position**”, is measured in terms of **ranking**.

Ranking is referred to a single webpage, but it is widely assumed that a whole website's ranking is that website's **home page** ranking.

To quote Wikipedia, “a good ranking in the search engines provides a steady supply of interested visitors/customers, while a poor one sinks any idea into oblivion.”

There is a whole industry called **SEO**, **Search Engine Optimization**, dedicated to obtain good web rankings.

The original and simplest **unit of measure** for ranking is Google's **PageRank**.

Although Google has officially abandoned it, and relies on more ranking technics now, PageRank is still at work.

# PageRank

To quote Wikipedia once again,  
“PageRank is a **link analysis algorithm** – named after Larry Page and used by the Google Internet search engine – that assigns a numerical **weighting** to each element of a hyperlinked set of documents, such as the World Wide Web, with the purpose of measuring its relative **importance** within the set.”

The PageRank scale of weight is simply 0/10.

image credit to NetLogo

# PageRank: industry and academia

The PageRank algorithm may be applied to any collection of entities with reciprocal quotations and references.

The name “PageRank” is a **trademark** of **Google**, and the PageRank process has been patented (U.S. Patent 6,285,999).

However, the patent was assigned to **Stanford University** and not to Google. **Google had exclusive license rights** on the patent from Stanford University.

The university received 1.8 million shares of Google in exchange for use of the patent; the shares were sold in 2005 for \$336 millions.

By the way, the patent formally expired in 2019.

# Ranking tools

How do we come to know the **rank** of a specific webpage, or – somehow – of a specific website?

Some dedicated **tools** are available on the Web, to retrieve information on how and how much webpages and websites are visited. A popular tool like these is **SimilarWeb**.

Moreover, some **toolbars** exist, that provide a relatively comprehensive access to this sort of ranking data. For instance, SimilarWeb is also available as a Firefox Add-On.

(Please take note, however, that SimilarWeb is a privacy-invasive platform.)

# Tim Berners-Lee

As most of us know, the **World Wide Web** is an **internet-based hypermedia** initiative for global information sharing.

It was invented by **Tim Berners-Lee**, a graduate from Oxford, while at CERN, the European Particle Physics Laboratory, in 1989.

Berners-Lee wrote the first **web client and server** in 1990. His specifications of URIs (Uniform Resource Identifier, which in the case of webpages are called **URL**, Uniform Resource Locator), **http** and **html** were refined as Web technology spread.

If the **Web** exists, it's because of **Europe**. Its rules, or **recommendations**, are run by the **W3C**, <https://www.w3.org/>

# Web 1.0 and Web 2.0

The original Web ambience – now commonly referred to as “Web 1.0” – has gradually turned into a more complex world, where **interaction**, **multimedia** and **databases** have made their appearance.

This shift has been informally called “Web 2.0” after a 2005 definition by **Tim O’Reilly**.

Web 1.0		Web 2.0
DoubleClick	-->	Google AdSense
Ofoto	-->	Flickr
Akamai	-->	BitTorrent
mp3.com	-->	Napster
Britannica Online	-->	Wikipedia
personal websites	-->	blogging
evite	-->	upcoming.org and EVDB
domain name speculation	-->	search engine optimization
page views	-->	cost per click
screen scraping	-->	web services
publishing	-->	participation
content management systems	-->	wikis
directories (taxonomy)	-->	tagging (“folksonomy”)
stickiness	-->	syndication

# Dynamic websites

Perhaps the most radical shift between the “Web 1.0” and the “Web 2.0” has been rooted in massive dependence upon databases.

The original websites were simply text (words, pictures, diagrams etc.) written in html language once and for all. They were static.

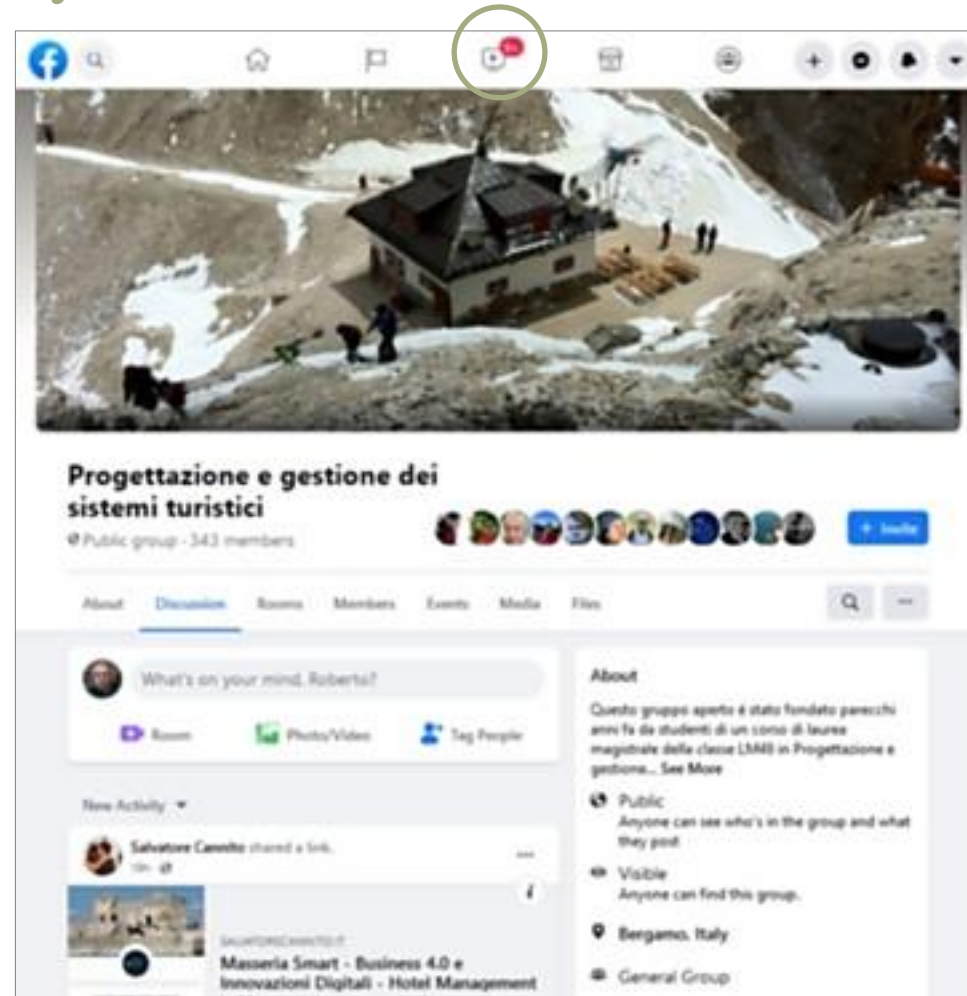

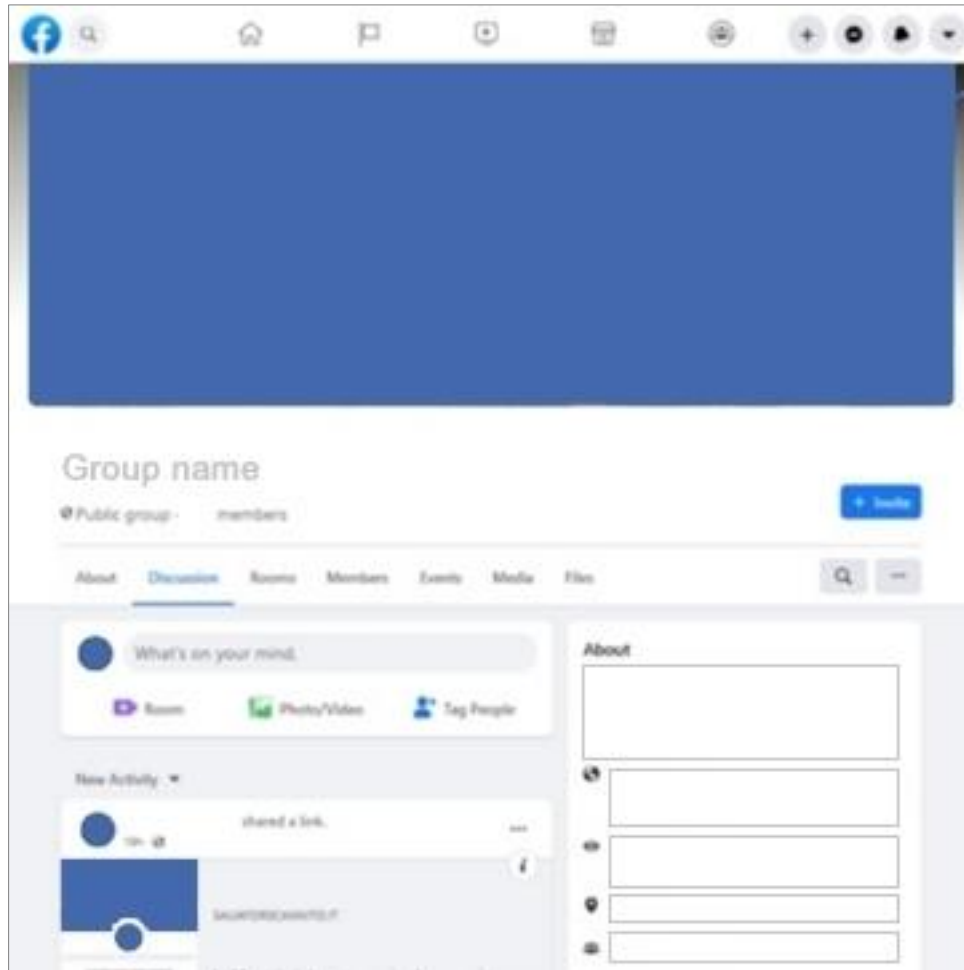

Most websites today are dynamic, instead. Each webpage’s content is not there once and for all. Rather, its content is generated on the fly from the content of a database.

The webpages’ layout is provided by a template, while each webpage’s content is generated on the fly from the content of records stored in a database.

Let’s consider an example of an empty template and its populated version.

# A template, and its dynamic content

Facebook takes from their databases highly specific content for every position in the template, triggers included.

# What are databases?

“Databases are organized collections of data. The data are typically organized to model relevant aspects of reality (for example, the availability of rooms in hotels), in a way that supports processes requiring this information (for example, finding a hotel with vacancies).” By the way, this is again Wikipedia...

The screenshot displays a database interface with a table of Points of Interest (POIs) and a field properties dialog box.

Tables have their structures, where descriptions of the fields are specified. Fields can have different formats: numbers, text, memos, Yes/No, dates, etc.

# Metadata

A database structure is a good example of metadata, that is, well... data about data or, if you prefer, categories under which data are organized.

Another example may be the pictures' properties, like in the Sony PlayMemories application.

# Relationships among tables

In a typical database, tables have reciprocal relationships.

The example shows that in this database the table which lists **Points of Interest** (like hotels) is associated with a different table which lists **Districts**.

In the example, each field in the table of POIs is associated (it must be so) with a field in the table of Districts.

Every POI record is associated with a single District record.

# Queries (or views)

We never happen to consider all the content of a database at the same time. We invariably ask a database to show which records (or which data from which records) correspond to a current question of ours. This question is called a query. For instance, we can ask a database to show us which events are expected to be available today in a place called “Odeon”.

To do so, we run a query which extracts from the database only the events that

- are listed in the table which lists events
- have begun on a date before today, and will end on a date after today
- are associated with a record in the table of places
- has the word “Odeon” as the content of the “Name” field in the table of places.

In some operating systems, the results of queries are now called views.

# Data, back offices and dynamic websites

If we upload a database on a web server, we can build a **back office** allowing us to manage the database online. This way we manage our official website's content, too. A back office is a tool allowing us, well... to run an office from its back!

This backoffice works best with Mozilla Firefox.  
If you don't use Firefox, you may happen to lose some of your work, due to the refresh function which allows you long update sessions.

# Data, UGC, and communities

If you wonder how **User-Generated Content (UGC)** is stored, managed and retrieved in web platforms, the answer is **through databases**.

By the way, UGC is defined as “**any form** of content such as blogs, wikis, discussion forums, posts, chats, tweets, podcasts, digital images, video, audio files, advertisements and other forms of media that was **created by users** of an online system.”

image credits to  
insidemarketing,  
slideshare and  
fulltiltmarketing

**Communities**, as you certainly know, are **platforms** where users are invited to share **UGC** about a specific field or in a set of specific digital formats.

# Communities: Flickr

Flickr (pronounced “flicker”) is an **image** hosting and video hosting service suite as well as an online community.

It was created by Ludicorp, a Canadian company, in 2004 and **acquired by Yahoo** in 2005. It currently belongs to SmugMug.

In addition to being a popular website for users to share and embed personal photographs, the service is widely used by **photo researchers** and bloggers to host images that they embed in blogs and social media.

# Communities: YouTube

YouTube is a **video-sharing** website created by former PayPal employees in February 2005. In October 2006, it was bought by **Google** for US\$1.65 billion.

YouTube is currently reckoned to be the second-most popular website in the world.

The website allows to **upload, view, rate, share, report** and **comment on** videos. It sticks to the official html5 recommendations to display a wide variety of user-generated and corporate videos.

- YouTube videos are often **embedded** in others' webpages.

# Communities: TikTok

TikTok is a Chinese **video-sharing** social networking service launched in 2017. It is owned by ByteDance, a Beijing-based Internet technology company founded in 2012 by Zhang Yiming.

TikTok is known in China as Douyin.

TikTok is used to create short music, lip-sync, dance, comedy and talent videos.

In July 2020, TikTok, excluding Douyin, reported close to 800 million monthly active users worldwide.

# Communities: TripAdvisor, of course

TripAdvisor is a brand of Tripadvisor, Inc., an online travel company headquartered in Needham, Massachusetts.

It claims to be **the largest travel site in the world**, reported to feature approximately 859 million reviews and opinions on some 8.6 million establishments – including 1.4 million accommodations, 842,000 rental properties, and 5.2 million restaurants.

TripAdvisor was founded in February 2000 and purchased by IAC/InterActiveCorp in 2004. IAC spun off its travel group of businesses under the **Expedia**, Inc. name in August 2005. TripAdvisor was spun off from Expedia in December 2011.

# Communities: LinkedIn

LinkedIn is a **business** and employment-oriented **online service** that operates via websites and mobile apps.

Launched in 2003, it is mainly used for professional networking. LinkedIn allows members (both workers and employers) to create profiles and “connections” to each other in an online network which is supposed to represent real-world professional relationships.

As of June 2021, LinkedIn is reported to have 756 million members from some 200 countries.

**Microsoft** acquired LinkedIn for \$26.2 billion in 2016.

# Social networks

Now, leaving the communities and moving on to the **social networks**, let's quote Wikipedia again.

“A social networking service is an online service, **platform**, or site that focuses on facilitating the building of social **networks** or social relations **among people** who, **for example**, share interests, activities, backgrounds, or real-life connections.

A social network service consists of a representation of each user (often a **profile**), his/her social links, and a variety of additional services.”

# Social networks: Facebook

Facebook is a **for-profit corporation** and online social media and social networking service based in Menlo Park, California. The Facebook website was launched on February 4, 2004, by **Mark Zuckerberg**, along with four fellow Harvard College students.

As of 2020, Facebook claimed 2.8 billion monthly active users, and ranked seventh in global internet usage.

The company has been subject to **repeated litigation**. An example: the Federal Trade Commission and a coalition of New York state and 47 other state and regional governments filed separate suits against Facebook on December 9, 2020, seeking **antitrust** action.

# Social networks: Twitter

Twitter is an online social networking service launched in 2006 and based in San Francisco, California. It enables users to send and read **short 140-(or 280-) character messages** called “tweets”.

Registered users can read and post tweets, but those who are unregistered can only read them.

In early 2019, Twitter was reported to have more than 330 million monthly active users.

On the day of the 2016 U.S. presidential election, Twitter proved to be **the largest source of breaking news**, with 40 million tweets sent by 10 pm that day.

# Social networks: SnapChat

Snapchat is an instant **messaging** and multimedia **mobile application** created by Evan Spiegel, Bobby Murphy, and Reggie Brown when they were students at Stanford University.

Snapchat evolved into a mix of private messaging and public content, including brand networks, publications, and live events such as sports and music.

Nevertheless, according to survey studies conducted in March 2016, the **personal oriented messaging** was still being accessed by users **more than the publicly offered content** that was being presented.

As of July 2021, Snapchat was reported to have 293 million daily active users, a 23% growth over a year.

# Between communities and social

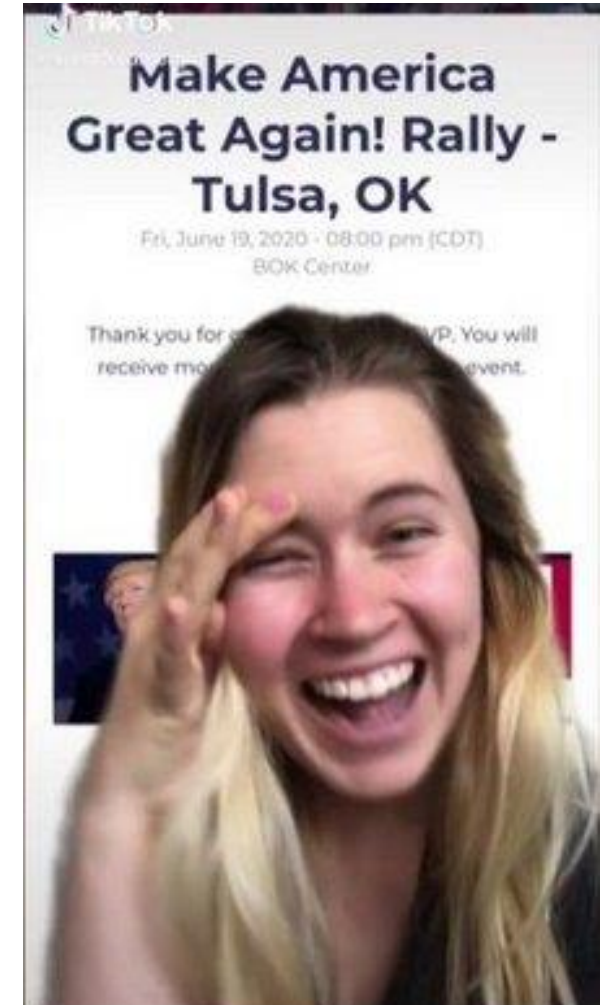

It may be interesting to note that Instagram, YouTube and TikTok – which are all **communities** born to deal with a specific medium only – have evolved to become **social networking** platforms.

For instance, TikTok was used **to spoil a political rally** organized by Mr Trump in June 2020, in what certainly was not a simple sharing of short videos.

This might make us consider the power of **images** and **moving images** as greater than that of other texts.

At least another case can be found of a visual community which has, as a matter of fact, become a social network.

# Community & social network: Instagram

Instagram is a **mobile**, desktop, and Internet-based **photo-sharing** application and service that allows users to share pictures and videos either publicly or privately.

It was created by Kevin Systrom and Mike Krieger and launched in October 2010 as a **free mobile app** exclusively for the iOS operating system. A version for Android devices was released two years later.

Instagram was **acquired by Facebook** in April 2012 for approximately US\$1 billion in cash and stock.

As of January 2019, the **Stories** feature is reported to be used by **500 million people daily**.

# Community & journalism: Medium

Medium is an online publishing platform developed by Twitter co-founder Evan Williams in August 2012 and owned by A Medium Corporation.

The platform is an example of social journalism, having a hybrid collection of amateur and professional people and publications, or exclusive blogs or publishers on Medium and is regularly regarded as a blog host.

The number of articles which are readable free by registered users is limited. In July 2020, Medium declared to have gathered around 400,000 paying members.

# Sharing tools: Google Drive

Beyond communities and social networking platforms, other sorts of web sharing **tools** must be mentioned, when talking about networks.

Perhaps the most useful of these tools is Google Drive, a file **storage** and **synchronization** service created by Google.

It allows users to store files in the cloud, **synchronize** files across devices, and share files. It encompasses Google Docs, Sheets and Slides, an **office suite** that permits **collaborative** editing of documents.

# Sharing tools: Dropbox, and WeTransfer

Another useful web tool is Dropbox, a file hosting service operated by Dropbox, Inc., headquartered in San Francisco, California, that offers cloud storage, file synchronization, personal cloud, and client software.

A service frequently used to share heavy files – as an alternative to Dropbox – is WeTransfer, a cloud-based service which was founded in Amsterdam in 2009.

WeTransfer does not necessarily store content. It simply makes it available to one or more specific users for a limited amount of time.

# Sharing tools: Slack

Finally, Slack is a cloud-based **team collaboration tool** co-founded by Stewart Butterfield, Eric Costello, Cal Henderson, and Serguei Mourachov, and owned by Salesforce from July 2021.

Slack began as an internal tool used by Butterfield's company, Tiny Speck, in the development of Glitch, a now defunct online game.

The name is actually an acronym, which means, "**Searchable Log of All Conversation and Knowledge**".

# Sharing, no responsibilities

Intentionally, we don't mention here two sharing platforms that pair people with identities like phone numbers only, allow disturbing people with unwanted personal calls, or openly bypass responsibilities issues.

Identifying these platforms by their logos won't be difficult.

These platforms' intrinsic ability to conceal real identities – helping to cover people's tracks and responsibilities – makes them substantially unacceptable for tourism activities.

It is true that other social platforms or even the e-mail allow to adopt fake identities. Yet, WhatsApp's and Telegram's structural attitude to hide themselves looks frankly scary.

# Web presence

So, you see there's the Web, but there are not only websites.

When we have – as we'll certainly have – to consider what the Web tells and comments about something, we cannot consider only its official website.

We must think in terms of its web presence as a whole.

The web presence of any entity – a destination, for instance – includes

1. the official website run by the destination
2. the accounts officially run by the destination on TripAdvisor, Facebook, etc.
3. what other people publish about the destination on the communities and the social networks.

As we will see, web reputation also deals with this third form of web presence.

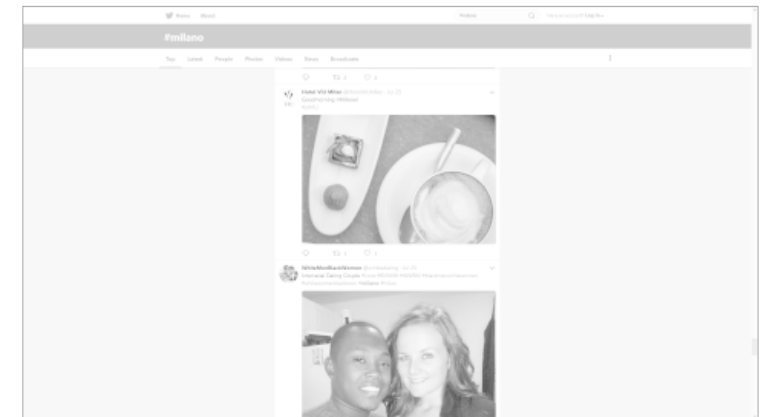

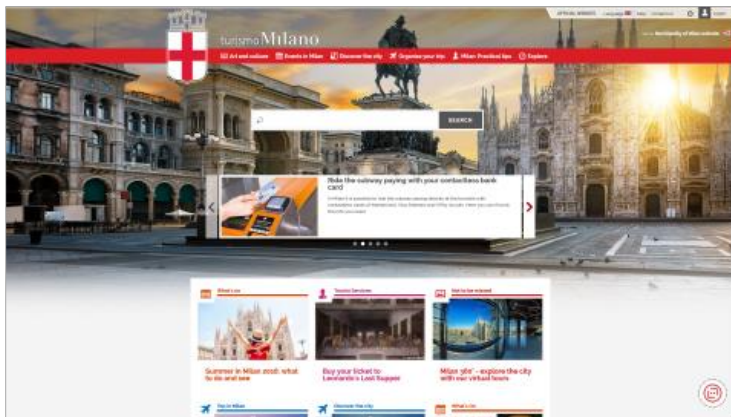

# In control

image credit to IconFinder

The web presence of any entity – a destination, for instance – includes

1. the official website run by the destination
2. the pages semi-officially run by the destination on TripAdvisor, Facebook, etc.
3. what other people write about the destination on the communities and the social networks.

# Partial control

image credit to IconFinder

The web presence of any entity – a destination, for instance – includes

1. the official website run by the destination
2. the pages semi-officially run by the destination on TripAdvisor, Facebook, etc.
3. what other people write about the destination on the communities and the social networks.

# No control

image credit to IconFinder

The web presence of any entity – a destination, for instance – includes

1. the official website run by the destination
2. the pages semi-officially run by the destination on TripAdvisor, Facebook, etc.
3. what other people write about the destination on the communities and the social networks.

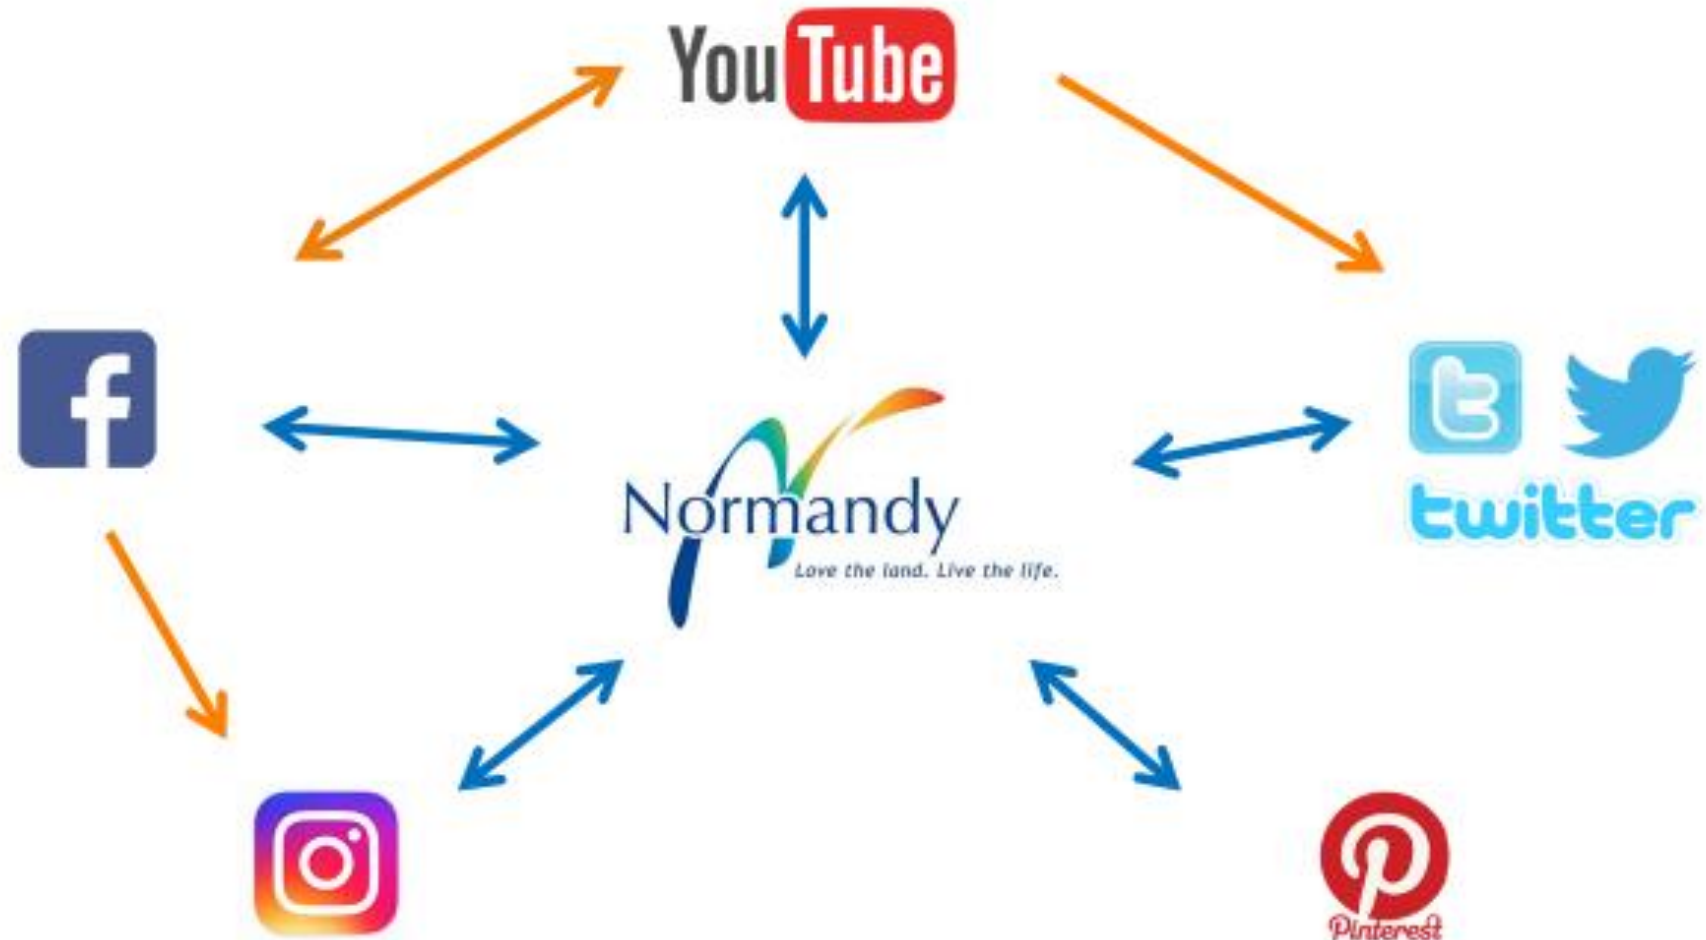

# A web presence map

image credit to IconFinder

A map of the links among the official and semi-official components of a web presence can be drawn.

This map of the official and semi-official web presence of Normandy was produced by colleagues of yours.

# Something is missing...

image credit to IconFinder

But this map lacks something, we realize...

A map of the links among the official and semi-official components should also include relations with TripAdvisor at least.

### About Normandy

Wide beaches along the "Flower Coast" attract families and those commemorating the D-Day landings of 1944. Inland, cattle graze in rural idylls and pre-WWII buildings stand alongside modern architecture. Rent a car or take tours from Caen or Bayeux. The landscape around his home in Giverny inspired Monet's Water Lilies, and summer's profusion of blooms is quite lovely. Don't miss Rouen's old town and cathedral, Caen's cathedral, Bayeux's tapestry and the ancient island-abbey of Mont-St-Michel.

Start planning for Normandy

Create a Trip to save and organize all of your travel ideas, and see them on a map

Create a Trip

Does Normandy manage its presence in TripAdvisor?

Does it monitor comments to know what guests think, judge and suggest? And, in case, does Normandy reply?

# Beyond our control!

image credit to IconFinder

Communities and socials are beyond our control. We can't access their servers.

- We can completely control our official website.
- We can partially control our TripAdvisor accounts, and our Facebook pages.
- We CAN'T control what other people write on TripAdvisor, Facebook, or Twitter or Instagram about us.

But if we want to improve – or at least defend – our reputation, we must know what other people write on the communities and the social networks about us.

But what is reputation about? And how can we know what other people write about us? We will discuss this later.

# Key points

1. Thinking in terms of networks may be helpful
2. Most networks are scale-free, and have hubs
3. The more we link, the more we are present
4. Web ranking is measurable, and can be optimized
5. Metadata are data about data, and help organizing data
6. Databases collect and manage data
7. Our web presence goes beyond our official websites & our socials
